Research Overview

My research focuses on designing and building networked systems that improve security and privacy, enhance performance, and provide insight into networks using emerging machine learning methods. My research is rooted in deep expertise in protocols and architectures that are used at massive scales and underpin modern connectivity. My work achieves broad impact through the design, implementation, deployment, and commercialization of fundamentally new techniques, architectures, systems, and protocols in practice; employing a "dirty-slate" approach to networked systems research for immediate applicability.

Education

Degree	Year	University	Field
Ph.D.	2017	University of California, Santa Barbara Santa Barbara, CA *Dissertation:* Network Measurement and Systems for Resource-Constrained Environments *Advisor:* Elizabeth Belding	Computer Science
M.S.	2011	University of St. Thomas St. Paul, MN	Software Engineering
B.A.	2009	University of St. Thomas St. Paul, MN	Computer Science

Positions

Title	Organization	Years
Assistant Professor	California Polytechnic State University	*January 2025–Present*
Principal Investigator	International Computer Science Institute	*June 2024–Present*
Assistant Professor	University of Hawaiʻi at Mānoa	*August 2022–December 2024*
Co-Founder and CEO	INVISV	*August 2020–December 2025*
Research Computer Scientist	Information Sciences Institute	*July 2021–May 2022*
Associate Research Scholar	Princeton University (CITP)	*June 2019–July 2021*
Postdoctoral Researcher	Princeton University (CITP)	*July 2017–June 2019*
Research Assistant (Ph.D.)	University of California, Santa Barbara	*2012–2017*

Software

Ongoing and Maintained Software

- *pcapML (github.com/nprint/pcapml)*. pcapML is an open-source tool that standardizes network traffic analysis by embedding metadata directly into packet captures. It supports both live eBPF-based packet capture with automatic process labeling and offline labeling using BPF filter rules, splitting labeled traffic into per-sample datasets ready for machine learning workflows.

- *L4Proxy (https://github.com/Invisv-Privacy/l4proxy)*. L4Proxy is a high-performance first-hop MASQUE proxy Network Function Virtualization (NFV) module. L4Proxy provides server-side functionality needed for running a Multi-Party Relay service to protect users' network privacy.

- *nPrint (nprint.github.io/nprint)*. nPrint is a standard data representation for network traffic meant to be directly usable with machine learning algorithms, replacing feature engineering for a wide array of traffic analysis problems. nPrint encodes data in a normalized, bit-aligned, space-efficient format that facilitates representation learning which automatically discovers the semantically important portions of network packets.

Older Projects

- *PGPP.* Pretty Good Phone Privacy (PGPP) is a fundamentally new cellular network architecture that provides users with location anonymity from the cellular carrier itself. By implementing our design, a cellular carrier no longer has the ability to track and record (and subsequently monetize) individual users' location history. PGPP is a core technology behind INVISV, a venture backed privacy-focused startup.

- *NetMicroscope.* NetMicroscope supports passive measurement for a wide variety of services and network scenarios. The system has two components: (1) a packet processing module that measures flow statistics and tracks their state at line rate; and (2) a quality inference module that queries the flow cache to obtain flow statistics and derive the service quality for tracked applications. We deployed this software in 50 user homes in the United States and France and worked with the Wall Street Journal to publish investigations made possible by NetMicroscope, including how video quality relates to access ISP speed. NetMicroscope led to the creation of a startup.

- *Oblivious DNS.* ODNS increases DNS privacy that (1) obfuscates the queries that a recursive resolver sees from the clients that issue DNS queries; and (2) obfuscates the client's IP address from upper levels of the DNS hierarchy that ultimately resolve the query (i.e., the authoritative servers). ODNS operates in the context of the existing DNS protocol, allowing the existing deployed infrastructure to remain unchanged. ODNS resulted in an IETF draft ("Oblivious DNS - Strong Privacy for DNS Queries"), has led to multiple industry-authored IETF drafts ("Oblivious DNS Over HTTPS", "Adaptive DNS Privacy"), and its underlying techniques have been implemented by Cloudflare, Apple, and Fastly, among others[1].

- *HybridCell*. A system that enables coexistence between commercial and local cellular coverage to augment poorly performing infrastructure. HybridCell monitors nearby commercial cellular networks and dynamically adjusts local network usage based on the "health" of the commercial network.

- *Cellular congestion detection*. A system and algorithm for passive detection and characterization of cellular base station radio congestion. The system has been used in measurement campaigns in rural Guatemala and large refugee camps in Uganda and Jordan by the United Nations and USAID. Our findings allowed local organizations to approach carriers to improve connectivity.

- *AirPress*. A system that allows for one-pass spectrum characterization. AirPress employs wavelet decomposition to achieve rapid transmitter detection in low and high noise environments.

- *WISPR*. A network protocol, WISPR (Wireless Internet Service Providers with Redundancy), that enables multipath over low-cost, heterogeneous wireless links.

- *VillageCache*. A system that transparently scrapes uploads and redelivers locally-created media in users' web sessions without accessing the Internet bottleneck link for poorly-connected networks.
